I was also interested in looking at GDP like Professor Eirich but with respect to the global peace index. #Are more peaceful countries generally wealthier than less peaceful ones?

df[['wdi_gdpcapcon2015']].describe()

1. Run a simple bivariate regression, and interpret the results. Did the results fit your expectations? Why, why not?

```
#bivariate OLS that accounts for NA values
corruption_gdp = smf.ols(formula = 'wdi_gdpcapcon2015~gpi_gpi', data = df, subset=df['gpi_gpi'].notna()).fit()
print(corruption_gdp.summary())
```

Notes

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

From the results, we see that every unit increase in the global peace index (1 being the most peaceful, and 5 being the least peaceful), GDP drops by approximately 20,210 USD. This is not surprising, as less peaceful countries are often less stable and violence and unrest can lead to the destruction or destabilization of economic and business infrastructure.

#quality of governance indicator variable
#scaled from 0 to 1, with 0 being low quality and 1 being the highest quality. Naturally, since this is on the opposite scale
#as the peace index variable, this code will reverse the scales to make sure the multivariate regression is interpretable.
df['new_icrg_qog'] = (1- df['icrg_qog'])*100
df[['new_icrg_qog']].describe()

```
df_filtered = df[['new_icrg_qog', 'gpi_gpi']].dropna()
stats.pearsonr(df_filtered['new_icrg_qog'], df_filtered['gpi_gpi'])
```

PearsonRResult(statistic=0.6779091170233515, pvalue=3.180268996950915e-19)

The two variables appear to have a moderate to strong positive correlation (0.677), so we will include them in the following multiple regression.

- 2. Add an additional variable that might mediate or partly "explain" the initial
- association from that simple regression above -- and explain your results. Did it work out? Yes? No?

corruption_actual_gdp = smf.ols(formula = 'wdi_gdpcapcon2015 ~ new_icrg_qog + gpi_gpi', data = df).fit()
print (corruption_actual_gdp.summary())

			:========

Notes:

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

We see that gpi_gpi is no longer significant, and the R^2 value has jumped significantly from 0.267 to 0.690. This indicates that the quality of governance is probably a mediator for global peace index and gdp. Overall, adding the qog variable seems to have worked out well in that it appears to show a clearer representation of the relationship between global peace index and gdp.

3. More on extreme combinations. Find the top 5 entities that are ranked at the top on one variable and ranked at the bottom on another variable. Interpret your results.

```
df['subjective_happiness_rank'] = df['ess_happy'].rank(ascending=False)
df['global_peace_index_rank'] = df['gpi_gpi'].rank(ascending=True)
extreme_comb = df[['cname', 'subjective_happiness_rank', 'global_peace_index_rank']].copy()
extreme_comb['rank_difference'] = extreme_comb['global_peace_index_rank'] - extreme_comb['subjective_happiness_rank']
extreme_sorted = extreme_comb.sort_values(by='rank_difference', ascending=False).head(5)
extreme sorted

```

We come to an interesting conclusion here, it seems that many of the happiest countries can also be the least peaceful, such as Israel and France given by the difference in ranks. We also notice this for Montenegro. Even though it is ranked 8th in terms of happiness, it seems to be less peaceful, but considering that the United Kingdom is only 15 ranks above it, it's possible that the scaling of the ranks is skewed in a way that is difficult to interpret from this table.
